DOCUMENTO NÚMERO 1. MEMORIA

CAPÍTULO 1. GENERALIDADES

1.1.- ANTECEDENTES Y OBJETO

El presente Estudio de Inundabilidad se redacta como complemento al documento del Plan General de Ordenación Urbanística del Término Municipal de Martos en la provincia de Jaén.

El objetivo del mismo es el de estudiar las llanuras de inundación de las avenidas ordinaria y extraordinaria de periodo de retorno 5 y 500 años respectivamente, del arroyo Larija del término municipal de Martos.

1.2.- ENCARGO

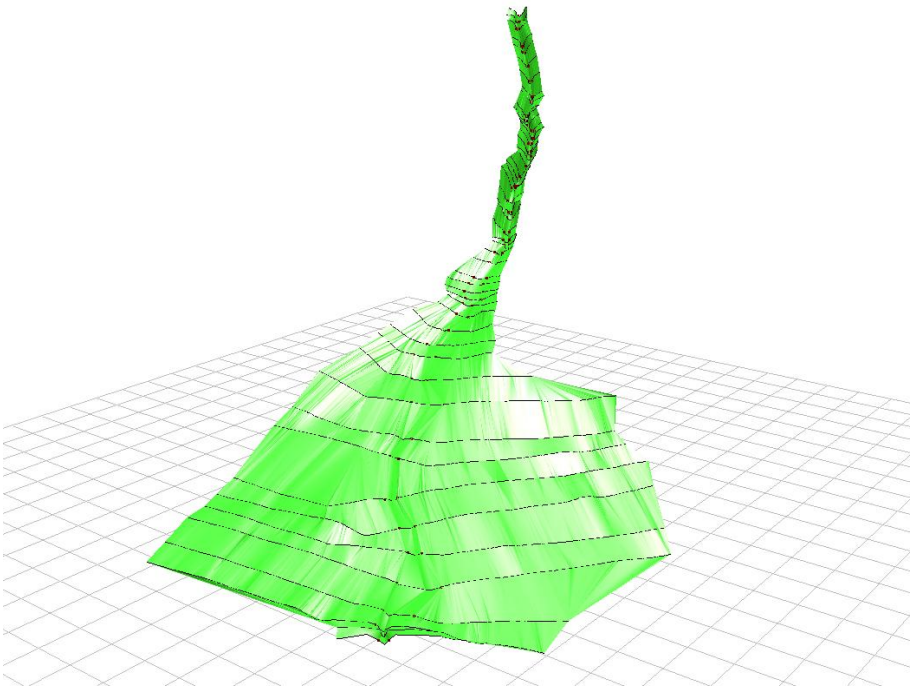
El presente documento se realiza por iniciativa de los arquitectos Antonio Estrella Lara y Jacinta Ortiz Miranda, redactores del mencionado Plan General de Ordenación Urbanística.

1.3.- ENTORNO DE ACTUACIÓN

El Arroyo Larija se encuentra ubicado al sureste del núcleo urbano de Martos. El tramo de estudio se inicia en la sección 1040 y finaliza en la 0, antes de la desembocadura del arroyo a la cuneta de la carretera JA-3305 (actual calle Príncipe Felipe), de Martos a Fuensanta de Martos. Se han modelizado 1040,92 metros de arroyo.

En total se han obtenido de la cartografía 51 secciones transversales con las que se ha generado el modelo digital del terreno para el cálculo de la llanura de inundación.

Ilustración 1. Modelo 3D del tramo del Arroyo Larija



La geometría media de este arroyo varía a lo largo del tramo debido a la orografía de la zona ya que pasa de ser un cauce muy encajado con una pendiente longitudinal muy elevada (cerca del

15%) a otra sección de menos profundidad y más abierta que ha obligado a la toma de secciones transversales de gran longitud y geometría heterogénea.

Las pendientes longitudinales, obtenidas a partir de la topografía con que contamos, resultan ser las siguientes:

- Pendiente media del tramo 8,40 %
- Pendiente inicial 17,00 %
- Pendiente final 5,00%

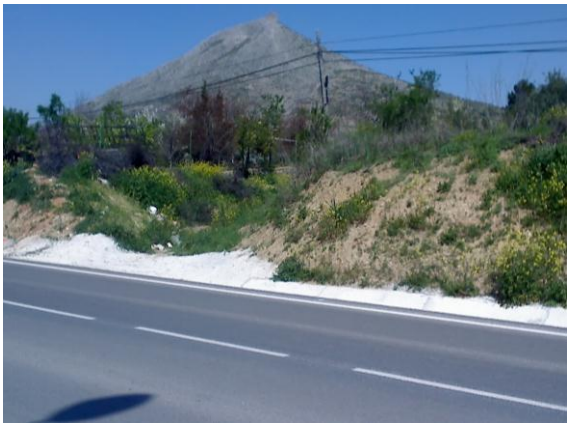
La vegetación, como puede comprobarse en las imágenes que siguen, no es excesiva en el cauce de aguas bajas. En cuanto a las márgenes son en su mayoría mosaicos de cultivos y olivares.

Se ha tenido en cuenta la presencia de estas masas arbustivas para la determinación del coeficiente de rugosidad, distinguiendo cauce principal y llanuras de inundación.

A continuación se muestran varias imágenes que caracterizan la zona.

Ilustración 2. Aspecto del cauce del arroyo Larija

Ilustración 3. Desembocadura a la cuneta de la carretera JA-3305



1.4.- BASES DE PARTIDA Y NORMATIVA DE APLICACIÓN

Como premisas previas se citan las isolíneas, en nuestro caso de precipitaciones máximas en 24h, publicados por la Dirección General de Carreteras en el texto "Máximas Precipitaciones de la España Peninsular" y el período de retorno a considerar.

Como es habitual se ha adoptado el período de retorno de 500 años para la avenida extraordinaria. A partir de ellos se realiza el cálculo del caudal de avenida.

En cuanto a normativa es de aplicación la Instrucción 5.2.IC, Orden de 14 de Mayo de 1.990 del Ministerio de Obras Públicas y Urbanismo.

CAPÍTULO 2. TRABAJOS REALIZADOS

2.1.- TOPOGRAFÍA

Se ha empleado la cartografía digital 1:2.000 de la Junta de Andalucía, proporcionada por el cliente. Concretamente se han utilizado las hojas E-946 27-29 y 27-30 para el Arroyo Larija.

2.2.- ESTUDIO HIDROLÓGICO

Partiendo, como ya se ha comentado, de las isolíneas, en nuestro caso de precipitaciones máximas en 24h, publicados por la Dirección General de Carreteras en el texto "Máximas Precipitaciones de la España Peninsular", se ha obtenido la lluvia de cálculo para el período de retorno considerado

Como la superficie de la cuencas es de 1 Km^2, se ha considerado un único punto de control o característico. La extrapolación se realiza para los periodos de retorno de 5 y 500 años A continuación transcribimos la tabla con los valores adoptados:

Tabla 1. Resumen de valores

COORDENADAS UTM DE PTOS ANALIZADOS		PRECIP. MAX DIARIAS PARA LOS PERIODOS DE RETORNO (mm/día)
PERIODOS DE RETORNO 5	416.848	57
	4.174.390	
PERIODOS DE RETORNO 500	416.848	140
	4.174.390	

Conocida la lluvia de cálculo, es preciso determinar las características físicas de la cuenca receptora.

Tabla 2. Caracterización de la cuenca

CUENCA	SUPERFICIE (HA)	PTO. ALTO CUENCA (M)	DISTANCIA (M)	PTO. ALTO CAUCE (M)	DIS.CAUCE (M)	PTO.BAJO (M)
ARROYO LARIJA	104	914	2150	835	1500	690

Careciéndose, como es lógico, de datos de aforo, el cálculo de caudal lo realizaremos por diversos métodos del tipo de los hidrometeorológicos, de forma que obtengamos una visión lo más amplia posible, que nos permita una definición acertada de los caudales previsibles.

Estos son los caudales resultantes para las avenidas de periodo de retorno 5 y 500 años:

Tabla 3. Resultados de cálculo

CUENCA	Q_5 (m^3/s)		Q_{500} (m^3/s)	
	Método Racional	Método 5.2-IC	Método Racional	Método 5.2-IC
Arroyo Larija	4,01	6,31	9,84	14,94

Adoptamos como valor de cálculo para el cálculo del DPH el proporcionado por el método de la Instrucción 5.2 I.C para el periodo de retorno de 5 años, fijando por tanto el caudal de cálculo en **6,31 m^3/s,** y para la llanura de inundación **14,94 m^3/s.**

2.3.- ESTUDIO HIDRÁULICO

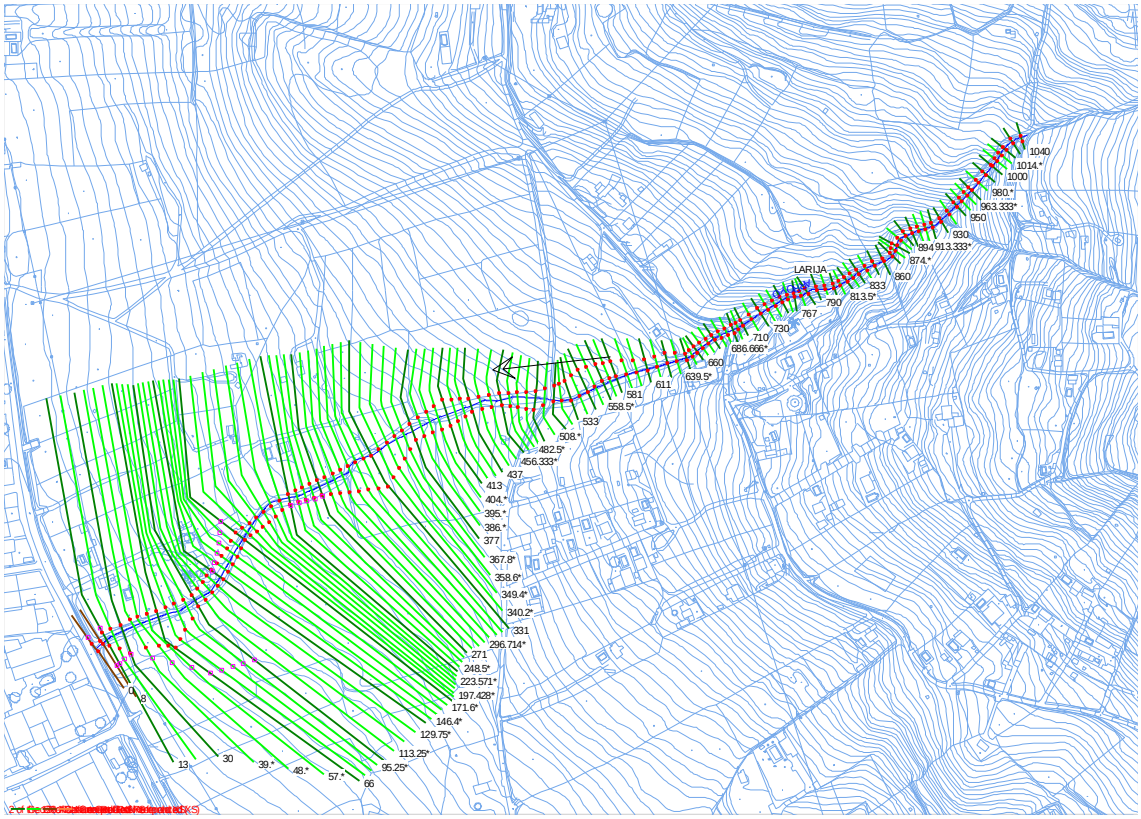
Determinados los caudales circulantes para las avenidas de periodo de retorno 5 y 500 años, procede el cálculo de la vehiculación de los tramos de estudio, empleando los programas informáticos HEC-Geo Ras y Hec-Ras (Sistema de Análisis de Río).

Para el cálculo anterior se ha de partir, además de la topografía del cauce y del caudal circulante, de otro parámetro básico y determinante, el coeficiente de Manning, valor dependiente de las condiciones físicas actuales de toda la llanura de inundación de los arroyos en los tramos de estudio.

Comentar que en el caso del Arroyo Larija la modelización ha sido bastante compleja debido a la topografía de la zona, que, en los últimos metros presenta un cauce poco encajado y por tanto, la llanura inunda buena parte de las márgenes.

Para afinar el modelo, se han interpolado secciones transversales a partir de las obtenidas en cartografía cada 10 m, tal y como muestra la siguiente imagen.

Ilustración 4.- Modelo interpolado empleado en el cálculo. En verde claro se muestran las secciones interpoladas.

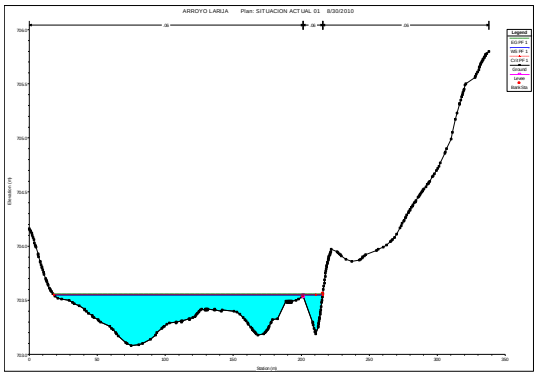


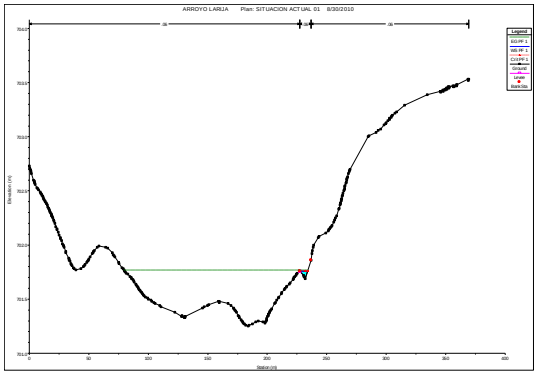
Antes de comentar los resultados obtenidos, es necesario aclarar que la precisión del modelo hidráulico no se corresponde con la precisión de la cartografía empleada, es decir, que como se ha partido de una cartografía a escala 1:2.000, con curvas de nivel equidistantes 1 metro, no podemos adoptar la escala milimétrica del modelo como valor absoluto.

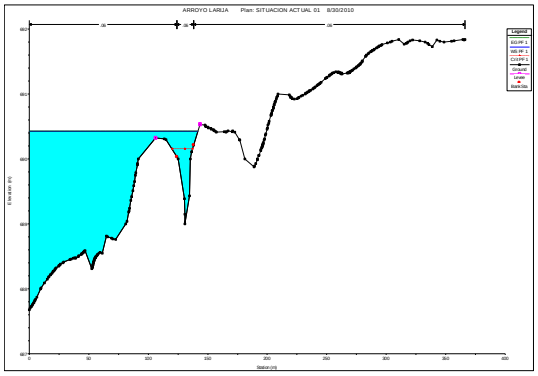
Ello nos ha llevado a adoptar motas en varias secciones para evitar que diferencias centimétricas entre el límite del cauce actual y la lámina de agua, extendiera la llanura de inundación varias decenas de metros. Estas motas se pueden consultar en el Apéndice 3, y en ningún caso superan los 20 cm, valor que entendemos razonable para el estudio de inundabilidad que nos ocupa, en el que se pretende delimitar la llanura de inundación de periodo de retorno 500 años.

A modo de ejemplo, transcribimos las tres secciones más representativas de este fenómeno:

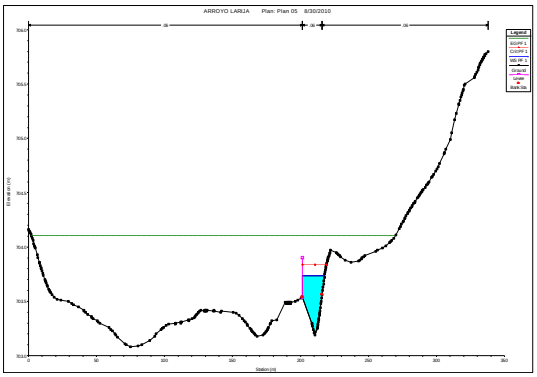
MODELO SIN MOTAS

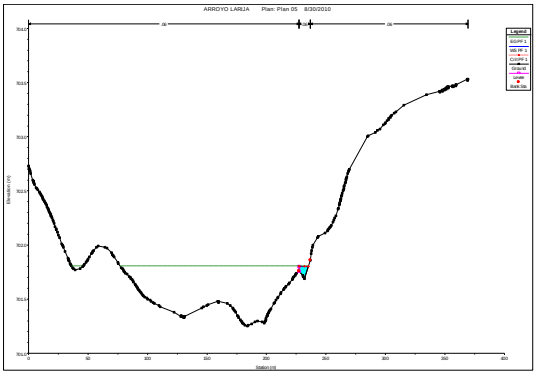


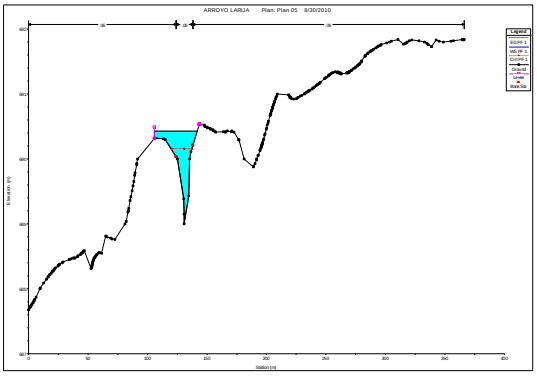




MODELO CON MOTAS ≤ 25cm







2.3.1.- AVENIDA ORDINARIA DE PERIODO DE RETORNO 5 AÑOS

El resumen de los datos obtenidos para el arroyo Larija modelizado se adjunta en la tabla e ilustraciones siguientes. Asimismo, se representa esquemáticamente la llanura de inundación para 5 años, remitiendo a los planos del presente Estudio para consulta de detalle.

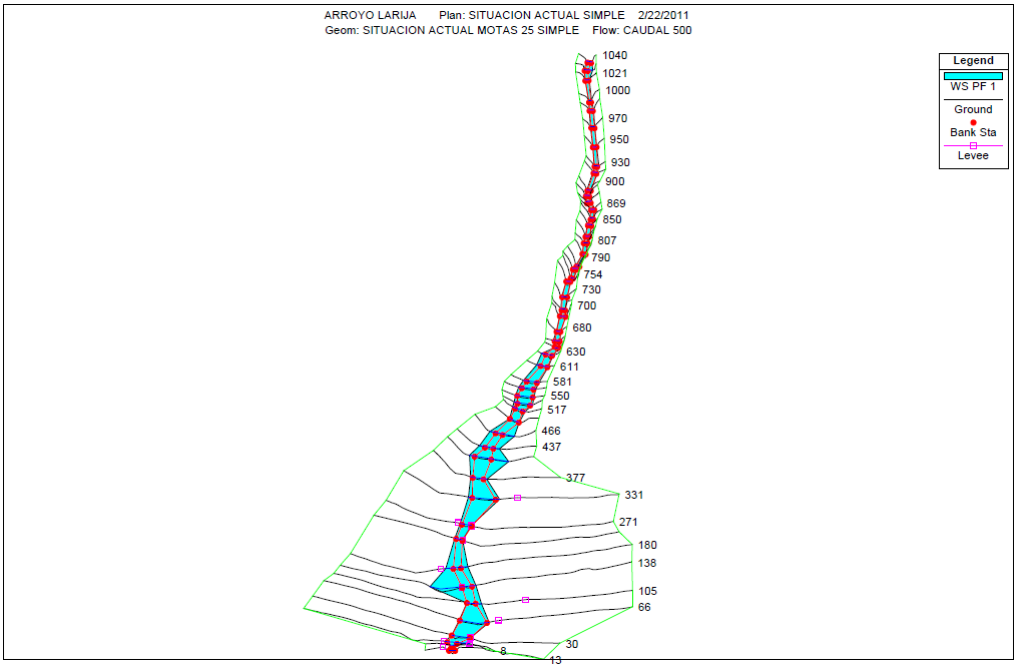
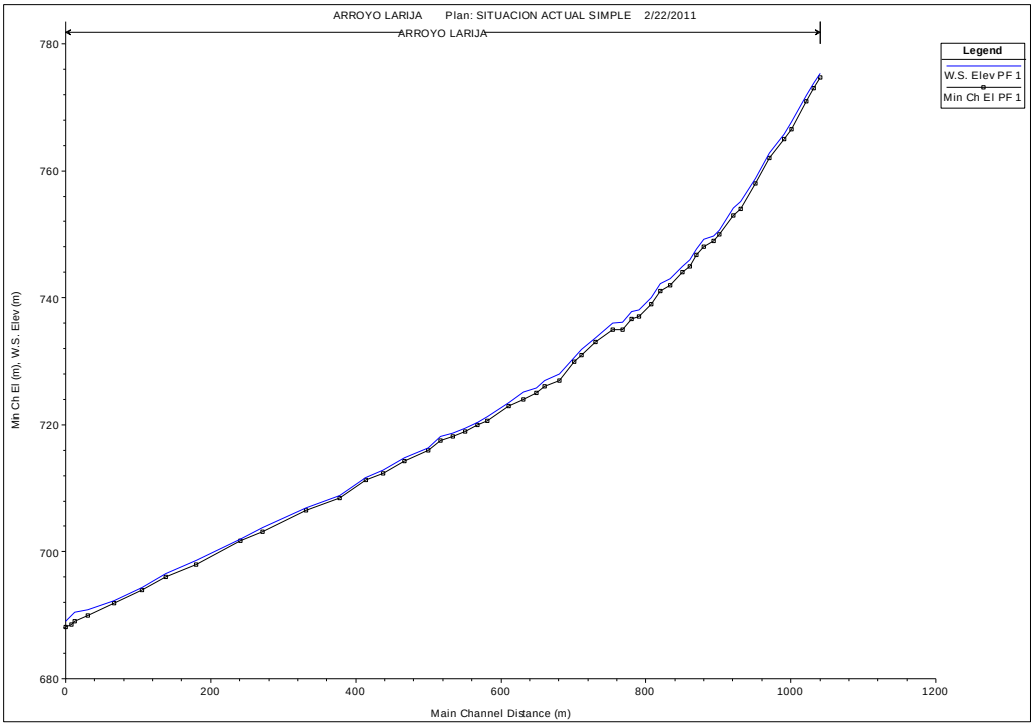
Ilustración 6. Perspectiva de la llanura de inundación del Arroyo Larija



2.4.- ANÁLISIS DE LOS RESULTADOS

A continuación se muestra el gráfico con las cotas de la llanura de inundación alcanzadas para la avenida extraordinaria de 500 años:

Ilustración 7. Cotas de inundación del modelo del Arroyo Larija



De este gráfico se extraen los valores de cota de lámina de agua en cada perfil para poder trasladarlos a planta y dibujar la llanura de inundación. Esta operación la realiza automáticamente la aplicación Geo-RAS, y el resultado ilustrativo queda recogido en el documento de Planos.

2.5.- INCIDENCIAS CON LA ORDENACIÓN EXISTENTE

Aunque este estudio complementa el documento del Plan General de Ordenación Urbanística en Martos y, por tanto, es en dicho documento donde se analizarán con detalle las posibles incidencias con la ordenación que se proponga, señalamos que, en el caso del Arroyo Larija, la llanura de inundación para la avenida extraordinaria afecta a lo largo de sus últimos 100 metros aproximadamente, a algunas edificaciones aisladas existentes en la zona.

La ordenación urbanística de los sectores de suelo urbanizable limítrofes al arroyo y a los terrenos inundables determinados en este estudio, tendrá en cuenta la integración paisajística con este espacio natural.

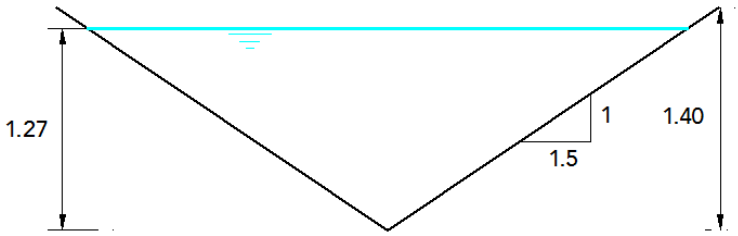
El modelo estudiado finaliza en la calle Príncipe Felipe, punto en el que el arroyo Larija se incorpora a la cuneta existente en la margen izquierda de la vía.

Ilustración 8. Desembocadura del Arroyo Larija a la cuneta de la JA-3305, denominada calle Príncipe Felipe

La capacidad actual de la cuneta no permite conducir la avenida extraordinaria de periodo de retorno 500 años del arroyo Larija.

Se hace necesaria, por tanto la ampliación de la cuneta. Se propone la siguiente sección tipo:

Ilustración 9. Propuesta acondicionamiento en tramo cuneta



Esta ampliación de la cuneta existente se integrará en el ámbito y en la ordenación de los sectores de suelo urbano no consolidado y urbanizable limítrofes.

2.6.- ORDENACIÓN DEL ESTUDIO Y DOCUMENTOS DE QUE CONSTA

El presente Estudio se ordena conforme a la siguiente documentación:

DOCUMENTO NÚMERO 1.- **MEMORIA** con 2 Anejos

Anejo número 1.- Estudio Hidrológico

Anejo número 2.- Estudio Hidráulico

DOCUMENTO NÚMERO 2.- **PLANOS**

2.1.- Plano de Situación e Índice

2.2.- Cartográfico de la zona

2.3.- Cuenca Hidrológica

2.4.- Delimitación del DPH

2.5.- Llanura de Inundación para T 500 años

2.7.- CONCLUSIÓN

Con cuanto antecede y el resto de documentación que se incorpora al presente Estudio, creemos haber explicitado suficientemente el alcance del presente trabajo y haber cumplimentado el encargo recibido, por lo que sometemos el Estudio a la tramitación correspondiente.

ANEJO NÚMERO 1. ESTUDIO HIDROLÓGICO

ANEJO NÚMERO 1. ESTUDIO HIDROLÓGICO

1. INTRODUCCIÓN

El objeto del presente anejo es calcular el caudal circulante para las avenidas ordinaria y extraordinaria de periodo de retorno 5 y 500 años respectivamente por el arroyo Larija, en Martos, a su paso por las posibles zonas de afección a la ordenación propuesta en el Plan General de Ordenación Urbana del municipio.

Para los cálculos que siguen a continuación, se hará uso de la información publicada por la Dirección General de Carreteras en el texto "Máximas Precipitaciones de la España Peninsular".

2. BASES DE CÁLCULO

2.1. LLUVIA DE CÁLCULO

Partiendo, como ya se ha comentado, de las isolíneas, en nuestro caso de precipitaciones máximas en 24h, publicados por la Dirección General de Carreteras en el texto "Máximas Precipitaciones de la España Peninsular", se ha obtenido la lluvia de cálculo para el período de retorno considerado.

2.2. PERIODO DE RETORNO

Al tratarse de un estudio de avenidas, se ha de definir el máximo período de retorno a considerar. Los valores que adoptan los diferentes autores varían según el tipo de cuenca y los daños previsibles, debiendo, además, tenerse en cuenta el criterio que establecen los Organismos competentes en materia hidrológica.

En el caso de cuencas mayores, con cauces ya conformados como es nuestro caso, los períodos de retorno se establecen entre 50 y 100 años pero teniendo en cuenta la normativa de la Agencia Andaluza del Agua, (en adelante AAA), se adopta para este caso el valor límite de 500 años.

Por tanto será el valor correspondiente al periodo de retorno de 500 años el empleado para fijar la llanura de inundación.

Para la determinación del DPH del cauce se ha empleado el periodo de retorno 5 años, si bien según nos indica la AAA en Jaén, suele estar comprendido entre 2 y 5 años.

Recordar que según el R.D.L. 1/01de 20 de julio, por el que se aprueba el Texto Refundido de la Ley de Aguas, y el R. D. 849/86, de 11 de abril, por el que se aprueba el Reglamento del Dominio Público Hidráulico que desarrolla los títulos preliminar, I, IV, V, VI y VII de la Ley 29/85, de 2 de agosto, de Aguas:

- álveo o cauce natural de una corriente continua o discontinua es el terreno cubierto por las aguas en las máximas crecidas ordinarias.
- Se considerara como caudal de la máxima crecida ordinaria la media de los máximos caudales anuales, en su régimen natural producidos durante diez años consecutivos, que sean representativos del comportamiento hidráulico de la corriente
- Se entiende por riberas las fajas laterales de los cauces públicos situadas por encima del nivel de aguas bajas, y por márgenes los terrenos que lindan con los cauces. Las márgenes están sujetas, en toda su extensión longitudinal:

a) A una zona de servidumbre de cinco metros de anchura, para uso público que se regulará reglamentariamente.

b) A una zona de policía de 100 metros de anchura en la que se condicionará el uso del suelo y las actividades que se desarrollen.

2.3. MÉTODO DE LAS "MÁXIMAS PRECIPITACIONES DE LA ESPAÑA PENINSULAR

Para la determinación de estos valores de máximas lluvias diarias se han seguido las siguientes fases:

- Recopilación de datos de las estaciones pluviométricas más significativas
- Tratamiento estadístico de las series de datos, realizando un modelo regional de parámetros y cuantiles
- Análisis de la distribución del valor medio de las series de máximas anuales

Mediante el ajuste estadístico SQRT-ET max de las citadas series de precipitaciones, se han extrapolado los valores al periodo de retorno considerado que se adjuntan en el Apéndices 1, " *Método de las Máximas Precipitaciones de la España Peninsular* ", del presente Anejo, mediante la aplicación informática MAXPLU, desarrollada igualmente por la Dirección General de Carreteras.

Esta aplicación se basa en la utilización de un sistema GIS de información geográfica tal que, a partir de las coordenadas geográficas o UTM del punto a analizar, transmite los parámetros resultantes de la extrapolación de los resultados del tratamiento estadísticos de los datos reales de las estaciones pluviométricas.

Como la superficie de la cuencas es ligeramente superior a 1 Km^2, se ha considerado un único punto de control o característico. La extrapolación se realiza para el periodo de retorno de 500 años. El análisis de los datos anteriormente citados, así como los resultados numéricos y gráficos obtenidos se adjuntan en el Apéndice anteriormente citado. A continuación transcribimos la tabla con el valor adoptado:

Tabla 1. Resumen de valores

COORDENADAS UTM DE PTOS ANALIZADOS		PRECIP. MAX DIARIAS PARA LOS PERIODOS DE RETORNO (mm/día)
PERIODOS DE RETORNO 5	416.848	57
	4.174.390	
PERIODOS DE RETORNO 500	416.848	140
	4.174.390	

Conocida la lluvia de cálculo, es preciso determinar las características físicas de la cuenca receptora.

3. CARACTERÍSTICAS DE LA CUENCA

Calculados los valores de la lluvia máxima de cálculo en el apartado anterior, abordaremos la determinación del resto de factores que intervienen en el cálculo del caudal de avenida, en definitiva, las características de la cuenca.

Nos interesan

- la superficie, que se determina sobre los planos a escala 1:10.000 de la Cartografía oficial de la Junta de Andalucía.
- los datos geométricos que determinan la topografía de la cuenca y del cauce: puntos altos, punto bajo (el de cruce con la conducción lógicamente) y longitudes a recorrer por el agua. Todos ellos se determinan también a partir de la cartografía antes citada.
- el coeficiente de escorrentía, para el cual partimos de los distintos tipos de cultivos existentes en la cuenca con sus extensiones superficiales correspondientes y del tipo de suelo. La cartografía citada y la inspección visual "in situ" son nuestras bases de partida.

No entramos en el cálculo de cada uno de los valores anteriores, puesto que se resumen en la tabla siguiente, así como su correspondiente reseña gráfica materializada en el Plano de Cuencas que se acompaña en el Apéndice 2, donde se determina la divisoria en el punto más bajo del cauce que nos ocupa en la zona de actuación.

Tabla 2. Datos de la cuenca

CUENCA	SUPERFICIE (HA)	PTO. ALTO CUENCA (M)	DISTANCIA (M)	PTO. ALTO CAUCE (M)	DIS.CAUCE (M)	PTO.BAJO (M)
ARROYO LARIJA	104	914	2150	835	1500	690

4. CÁLCULO DEL CAUDAL DE AVENIDA

Teóricamente el caudal aportado por una cuenca en un punto vendrá determinado por la lluvia correspondiente al tiempo de concentración de la cuenca, afectando a la superficie de la cuenca y reducida por la aplicación de coeficientes de escorrentía.

Según el nivel de seguridad deseable, función lógicamente de los posibles riesgos, se adoptará para la lluvia un periodo de retorno menor o mayor, entre los 10 años y los 1.000 años como valores habituales, adoptados ingenierilmente.

La AAA exige que se considere la lluvia de periodo de retorno de 500 años por lo que es para este valor para el que desarrollaremos los cálculos del presente Estudio. Como ya se ha comentado, para la determinación del DPH se usará la lluvia de periodo de retorno de 5 años.

De los mapas de Usos del Suelo publicados por la Junta de Andalucía, se ha extraído la información sobre el tipo y uso de los suelos afectados por la cuenca anterior. Esta información se empleará para el cálculo del coeficiente de escorrentía, como más adelante se detallará.

4.1. MÉTODOS DE CÁLCULO

Careciéndose, como es lógico, de datos de aforo, el cálculo de caudal lo realizaremos por métodos empíricos, de acuerdo con las formulaciones habituales para este tipo de

estimaciones. Dada la inseguridad de los mismos realizamos el cálculo por diversos métodos del tipo de los hidrometeorológicos, de forma que obtengamos una visión lo más amplia posible, que nos permita una definición acertada de los caudales previsibles.

4.1.1. MÉTODO RACIONAL

La sencilla formulación del Método Racional lo hace muy atrayente para los casos en los que no es preciso estudiar laminación y sólo interese el valor del caudal punta, que en este caso será de cálculo.

La expresión para el cálculo del caudal con este método es la siguiente:

$$Q = \frac{C \times I \times S}{K} \times K' \qquad \text{siendo,}$$

Q = Caudal de cálculo en m^3/seg

C = Coeficiente medio de escorrentía de la cuenca o superficie drenada

I = Intensidad media de precipitación correspondiente al periodo de retorno considerado y a un intervalo igual al tiempo de concentración, en mm/h

S = área de la cuenca en Km^2, a no ser que existan perdidas o aportaciones de importancia, tales como resurgencias o sumideros, en cuyo caso el cálculo del caudal Q deberá justificarse convenientemente.

K = coeficiente que depende de las unidades en las que se consideren los parámetros anteriormente descritos, en nuestro caso y para las unidades consignadas $K = 3,6$

K' = factor de corrección que adopta el valor de 1,2, atendiendo a que la hipótesis de lluvia neta constante admitida en el método racional no es real y en la práctica, existen variaciones en su reparto temporal que favorecen el desarrollo de los caudales punta. Sin embargo, en cuencas pequeñas (Tiempo de Concentración < 6h), la influencia de la variación temporal de la lluvia neta es secundaria y se puede reflejar con el factor K', con lo que la expresión inicial quedaría como sigue:

$$Q = \frac{C \times I \times S}{3,6} \times 1,2$$

En el caso normal de cuencas en las que predomine el tiempo de recorrido de flujo caracterizado por una red de cauces definidos, el tiempo de concentración Tc (horas), se obtiene de la expresión:

$$Tc = 0,3 \times \left[\left(\frac{L}{J^{0,25}} \right)^{0,76} \right]$$

Tc = tiempo de concentración (horas)

L = longitud del cauce principal (kms)

J = pendiente media del cauce principal (m/m)

La intensidad de lluvia correspondiente a una duración t viene determinada por la aplicación de la fórmula de Yarnell y Hattaway, con los coeficientes deducidos por Jaime Nadal para el caso de España, conforme ha sido publicado por el entonces denominado Instituto Eduardo Torroja. Obtenemos:

$$I_t = 9{,}25 \times I_h \times t^{-0{,}55}$$, donde

I_t = Intensidad para una duración del aguacero de (t minutos), en mm

I_h = Intensidad horaria, en mm

t = Duración del aguacero en minutos

Del análisis de los datos de lluvia se obtiene el valor de precipitación máxima diaria para un periodo de retorno determinado, y que en nuestro caso es de 500 años. La distribución de esta lluvia a lo largo del día no es conocida, y como ya se ha citado es constante, es decir que se supone que pasaríamos de datos de precipitación a intensidad, sin más que dividir entre 24 horas. Esta suposición es bastante errónea pues una vez que el aguacero alcanza una duración igual al tiempo de concentración de la cuenca, el caudal aportado por la cuenca no aumenta considerando que no se interrumpe el normal discurrir de las aguas. Al no disponer de datos suficientes para configurar el hidrograma de la cuenca vertiente para aguaceros de distinta duración y trabajar con valores de precipitación y no de intensidad, diremos que para calcular la Intensidad correspondiente al tiempo de concentración por la fórmula de Yarnell y Hattaway consideraremos que la intensidad horaria es el 25% de la diaria con lo que estamos suponiendo que es posible que las precipitaciones recogidas a lo largo de un día pueden haberse concentrado en tan sólo seis horas. De este modo la expresión que nos permite calcular la intensidad correspondiente a un tiempo de concentración dado queda como sigue:

$$I_t = 9{,}25 \times 0{,}25 \times Pmax_{24h} \times t^{-0{,}55}$$, donde

I_{Tc} = Intensidad correspondiente al tiempo de concentración y periodo de retorno considerados, en mm

Pmáx = Precipitación máxima diaria para el periodo de retorno considerado, en mm

Tc = Tiempo de concentración de la cuenca en estudio, en minutos

El último parámetro que nos queda por definir es el coeficiente de escorrentía que define la proporción de la componente superficial de la precipitación de intensidad I, y depende en líneas generales de las características de suelo, vegetación, topografía y precipitación.

Dado el tipo de cuenca considerado y de conformidad con los valores habituales podemos estimar el coeficiente de escorrentía por:

$$C = \frac{0{,}3 * t}{20 + t}$$

En nuestro caso, y dado que la estimación anterior proporciona unos valores muy bajos de C (0,2), se ha tomado un coeficiente de escorrentía de 0,65 para el arroyo Larija.

Los resultados obtenidos por aplicación de este método a la cuenca estudiada se recogen en el apéndice 2 del presente Documento. A continuación se presenta un resumen:

Tabla 3. Resumen de resultados por el Método Racional

T	Tc (h)	It (mm)	C	Q (m³/s)
5	0,64	17,78	0,65	4,01
500	0,64	43,67	0,65	9,84

4.1.2. MÉTODO DE LA INSTRUCCIÓN DE DRENAJE

Con fecha 23 de Mayo de 1.990, el B.O.E. publicaba la orden de 14 de mayo por la que se aprobaba la Instrucción 5.2 I.C. de Drenaje Superficial, que con independencia de ser concebida para la aplicación al drenaje de Carreteras, significa una aportación, a nuestro juicio muy valiosa, a los métodos de cálculo de avenidas, en casos simplificados de cuencas pequeñas.

Aplicamos también este método a los diferentes casos que nos ocupan, diferenciando como es lógico cada una de las cuencas estudiadas.

El tiempo de concentración es, según este método:

$$Tc = 0.3 \cdot \left(\frac{L}{J^{0.25}} \right)^{0.76}$$

La intensidad que recoge el método de la Instrucción de Carreteras, siempre considerando el periodo de retorno y tiempo de concentración considerados para el cálculo, adopta la siguiente expresión:

$$\frac{I_t}{I_d} = \left(\frac{I_1}{I_d} \right)^{\left(\frac{28^{0,1} - t^{0,1}}{28^{0,1} - 1} \right)}$$ donde,

I_t = intensidad media correspondiente al intervalo de duración t, en mm/h

I_d = intensidad media diaria correspondiente al periodo de retorno considerado Id=Pd/24 en mm/h

P_d = precipitación máxima diaria correspondiente al periodo de retorno considerado

I_1 = la intensidad horaria de precipitación correspondiente a dicho periodo de retorno

El valor del ratio $\frac{I_1}{I_d}$ se determina de la figura 2.2. de la Instrucción 5.2.- I.C, y si hacemos Tc=t en la expresión anterior se obtiene el valor de intensidad a emplear en el cálculo.

Ya se ha citado en a descripción del Método Racional, que el coeficiente de escorrentía, define la proporción de la componente superficial de la precipitación de intensidad, y que depende de la razón entre la precipitación diaria P_d correspondiente al periodo de retorno y el umbral de escorrentía P_0 a partir del cual se inicia esta, este umbral de escorrentía es característico de cada cuenca.

La formulación usada en este método está basada en el método propuesto por la Ley del Soil Conservation Service (USA) para las relaciones lluvia-escorrentía y que se corresponde a las siguientes expresiones:

$$E/P = 0 \qquad \text{si } (P/P_0)<1$$

$$E/P_0 = \frac{\left[\left(\frac{P}{P_0}\right)-1\right]^2}{\left(\frac{P}{P_0}\right)+4} \qquad \text{si } (P/P_0)>=1$$

Siendo:

E(mm) = escorrentía igualmente acumulada y provocada por P

P(mm) = precipitación acumulada desde el comienzo del aguacero hasta el instante dado

P_0(mm) = parámetro o umbral de escorrentía que define la precipitación total por debajo de la cual no se produce escorrentía.

El coeficiente de escorrentía C, en un instante dado hasta el cual ha precipitado P y se ha provocado una escorrentía E, se puede obtener derivando las expresiones anteriores:

$$C = \frac{dE}{dP} = \frac{d\left(\frac{E}{P_0}\right)}{d\left(\frac{P}{P_0}\right)} = \frac{\left(\frac{P}{P_0}-1\right)\times\left[\left(\frac{P}{P_0}+9\right)\right]}{\left[\left(\frac{P}{P_0}\right)+4\right]^2}$$

C va creciendo a lo largo del aguacero y su valor medio en un intervalo será mayor que el correspondiente a su origen y menor que el del final. El intervalo objeto de estudio es aquel que proporciona mayor escorrentía y se admite que corresponde al de duración igual al tiempo de concentración y que contiene al máximo del hietograma. Si se conoce el valor de P en dicho instante, la expresión anterior permitirá obtener el coeficiente de escorrentía buscado.

Se ha testado en varias estaciones pluviométricas españolas que puede admitirse una ley del tipo:

$$P_{máx.intensidad} = b \times P_d$$

donde b es un parámetro que refleja la posición relativa del intervalo de máxima intensidad dentro del pluviograma diario, y que puede admitirse que toma un valor de 0,5. Con esto, quedaría fijado el valor del coeficiente de escorrentía a utilizar en función de P_d.

Esta formulación debe ser corregida en los casos de aguaceros con pequeño periodo de retorno puesto que en estos casos no se cumple sistemáticamente la hipótesis básica: el máximo caudal no está asociado al intervalo de máxima intensidad y duración Tc, ya que dicha precipitación quedará absorbida íntegramente por el terreno al ser menor que el umbral de escorrentía.

En estos casos, el intervalo generador del máximo caudal, y con él, el punto intermedio indicativo del coeficiente de escorrentía, se desplazan en el tiempo hacia la zona final del aguacero, en espera de condiciones más desfavorables de la humedad del suelo que las correspondientes al intervalo de máxima intensidad.

Este problema se aborda modificando la ley anterior, resultado de la función derivada, en los entornos de los pequeños valores, haciéndola despegar del eje C = 0 para $P_d = P_0$, para tender posteriormente a confundirse con la curva primitiva, proponiéndose finalmente:

$$C = 0 \qquad \text{si } (P_d/P_0)<1$$

$$C = \frac{dE}{dP} = \frac{d\left(\frac{E}{P_0}\right)}{d\left(\frac{P}{P_0}\right)} = \frac{\left(\frac{P}{P_0}-1\right)\times\left[\left(\frac{P}{P_0}+23\right)\right]}{\left[\left(\frac{P}{P_0}\right)+11\right]^2}$$

La expresión propuesta en la Instrucción de Carreteras 5.2. para el cálculo del caudal, que se recoge en el apartado 2.2., es igual a usada en el método racional descrito en el apartado anterior y es:

$$Q = \frac{C \times I \times S}{3,6} \times 1,2 = Q = \frac{C \times I \times S}{3}$$

Los significados y unidades de las variables son los mismos que se han descrito anteriormente.

Siguiendo con las consideraciones del cálculo del coeficiente de escorrentía diremos que para el caso de cuencas heterogéneas deberán dividirse estas en cuencas parciales cuyos coeficientes parciales de escorrentía se calcularán por separado, reemplazando luego el término C x S de la fórmula anterior por la sumatoria de las cuencas parciales Σ(C x S).

El valor del umbral de escorrentía (P_0), en un sentido determinista, depende de las características de la cuenca y puede obtenerse (basándose en el concepto de "número de curva" del Soil Conservation Service) a partir de la tabla 2-1 de la Instrucción 5.2 I.C. de Drenaje superficial y de los siguientes datos:

- pendiente
- capacidad de infiltración del suelo
- vegetación
- características del laboreo

El valor obtenido de dicha tabla se deberá multiplicar por el coeficiente corrector dado en la figura 2.5. de la mencionada instrucción.

Este coeficiente refleja la variación regional de la humedad habitual en el suelo al comienzo de aguaceros significativo e incluye una mayoración (del orden del 100 %) para evitar sobrevaloraciones del caudal de referencia a causa de ciertas simplificaciones del tratamiento estadístico del Método Hidrometeorológico.

En el caso de que no se conozca con certeza el tipo de terrenos de la cuenca de estudio, se puede tomar simplificadamente un valor conservador de P_0 (sin tener que multiplicarlo luego por el coeficiente de la figura 2-5) igual a 20 mm, salvo en cuencas con rocas o suelos arcillosos muy someros, en las que se podrá tomar igual a 10 mm.

Tabla 4. Resumen de resultados por el Método de la 5.2-IC

T	Tc (h)	It (mm)	C	Q (m^3/s)
5	0,64	27,99	0,65	6,31
500	0,64	68,76	0,65	14,94

Los resultados obtenidos para la cuenca del arroyo Larija para cada uno de los periodos de retorno estudiados se recogen en el Apéndice 3 del presente Anejo.

4.2. VALOR ADOPTADO PARA EL QCAL

Se acompañan en el Apéndice 3 adjunto las salidas correspondientes a los diferentes métodos antedichos, conforme al cálculo numérico realizado por ordenador.

Es de mencionar que los cálculos realizados para la obtención en el Método Racional del Coeficiente de Escorrentía, dan como resultado valores inferiores a 0,65, considerado a juicio del proyectista demasiado bajo dado el entorno en el que nos encontramos, por lo que se ha realizado igualmente los cálculos considerando el valor del Coeficiente de Escorrentía 0,65 para el Arroyo Larija.

Por tanto, para una misma cuenca, se han considerado los valores de coeficiente de escorrentía teórico para el Método Racional (y viendo que son muy reducidos, se han adoptado unos valores superiores), y el valor obtenido por el Método de la Instrucción 5.2 I.C.

Como consecuencia de los cálculos antedichos resultan los siguientes caudales para la avenida de periodo de retorno de 500 años:

Tabla 5. Resultados de cálculo

CUENCA	Q_5 (m^3/s)		Q_{500} (m^3/s)	
	Método Racional	Método 5.2-IC	Método Racional	Método 5.2-IC
Arroyo Larija	4,01	6,31	9,84	14,94

Adoptamos como valor de cálculo para el cálculo del DPH el proporcionado por el método de la Instrucción 5.2 I.C para el periodo de retorno de 5 años, fijando por tanto el caudal de cálculo en **6,31 m^3/s,** y para la llanura de inundación **14,94 m^3/s.**

ANEJO NÚMERO 2. ESTUDIO HIDRÁULICO

ANEJO NÚMERO 2. ESTUDIO HIDRÁULICO

1. INTRODUCCIÓN

El objeto del presente Anejo es crear un modelo hidráulico del arroyo Larija, en Martos, para prever el régimen de flujo del mismo para la avenida ordinaria y para la máxima avenida extraordinaria o, lo que es lo mismo, para los caudales de cálculo. De este modo se fijarán parámetros tales como resguardos, velocidades, alturas de lámina de agua, etc.

Enumerados los datos de partida empleados en la modelización, se expondrán con detalle los pasos dados para obtener los niveles de avenida del arroyo en el tramo de estudio (en especial, modelado de secciones transversales, obras de fábrica, etc.), datos finales que nos permitirán obtener la llanura de inundación.

2. DATOS DE PARTIDA

2.1. CAUDALES

En el Anejo 1 del presente Estudio se realiza una exposición detallada de los distintos estudios hidrológicos realizados para determinar los caudales circulantes para las avenidas ordinaria y extraordinaria. Los caudales finalmente adoptados son:

Tabla 1. Caudales de cálculo para T=500 años

T	Q_{500} (m^3/s)
5	6,31
500	14,94

2.2. TOPOGRAFÍA

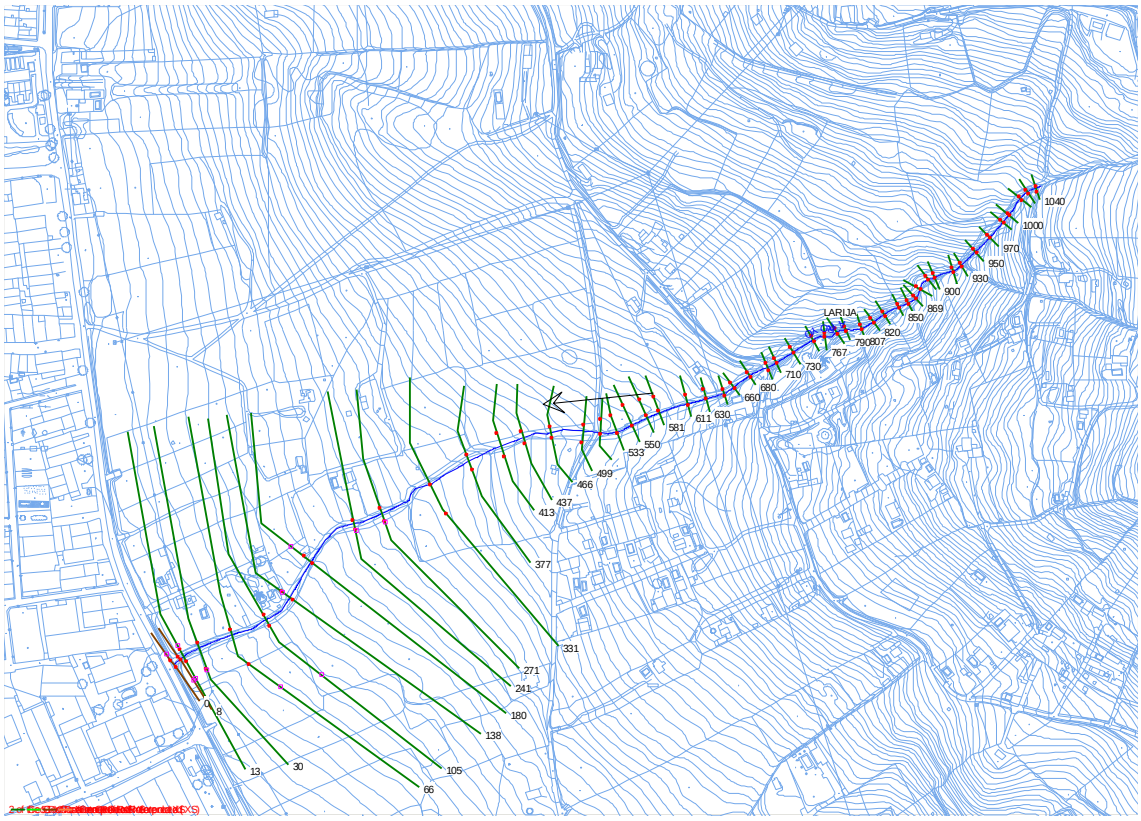
Se ha empleado la cartografía digital 1:2.000 de la Junta de Andalucía, proporcionada por el cliente. Concretamente se han utilizado las E-946 27-29 y 27-30 para el Arroyo Larija.

2.3. MODELO HIDRÁULICO DEL ARROYO LARIJA

2.3.1. SECCIONES MODELIZADAS

La descripción del modelo se efectúa en el sentido aguas arriba-aguas abajo. Las situaciones y secciones actuales del cauce (perfiles transversales) quedan reflejadas en el siguiente croquis:

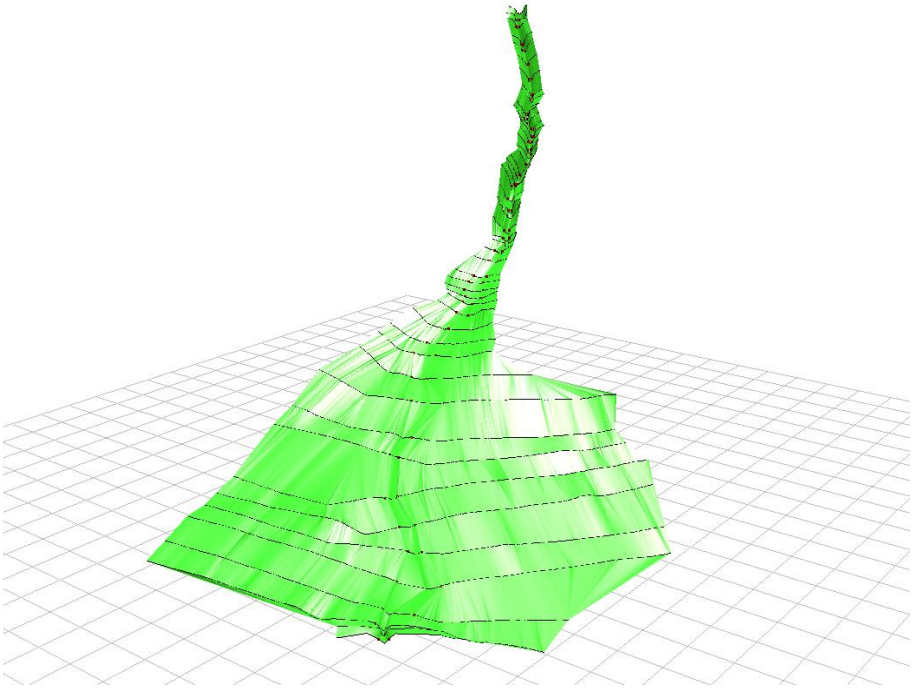
Ilustración 1. Esquema del Modelo Hidráulico del Arroyo Larija



El tramo se inicia en la sección 1040 y finaliza en la 0, habiéndose modelizado 1040,92 metros de arroyo. El tramo finaliza en la desembocadura del arroyo a la cuneta de la carretera JA-3305, de Martos a Fuensanta de Martos.

En total se han obtenido de la cartografía 51 secciones transversales con las que se ha generado el modelo digital del terreno para el cálculo de la llanura de inundación.

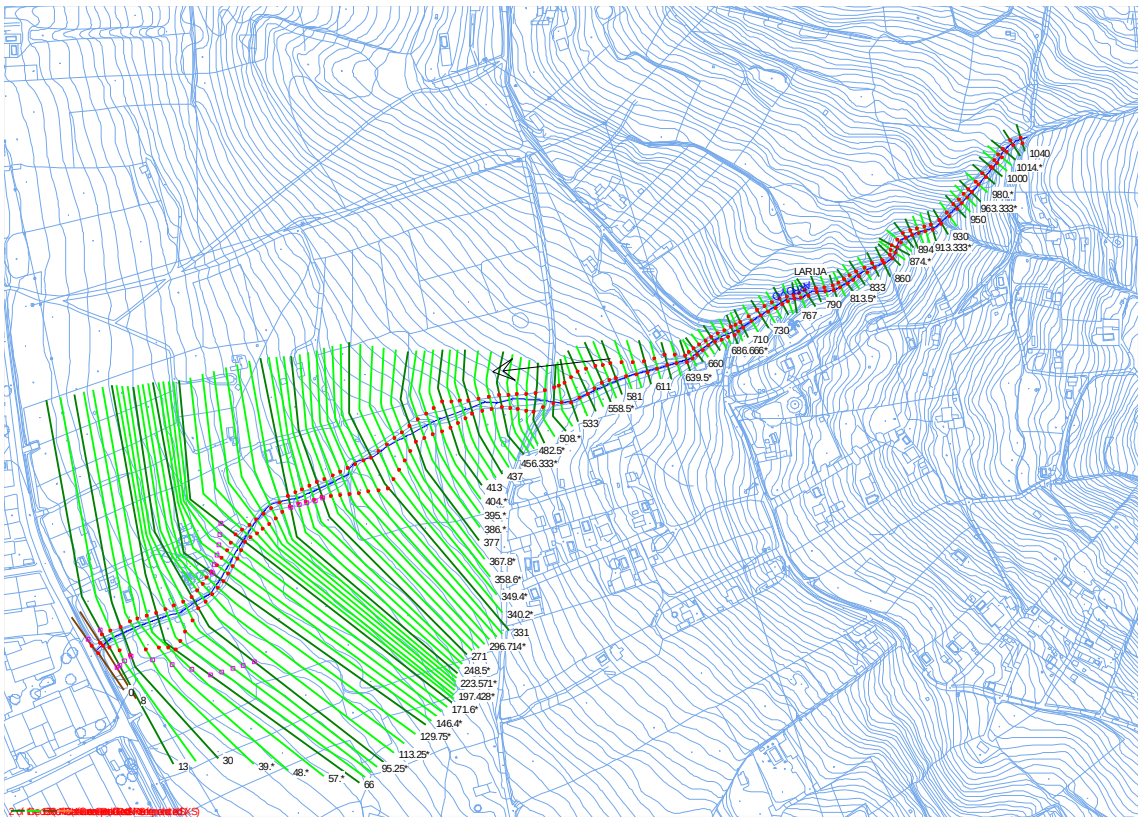
Ilustración 2. Modelo 3D del tramo



La geometría media de este arroyo varía a lo largo del tramo debido a la orografía de la zona ya que pasa de ser un cauce muy encajado con una pendiente longitudinal muy elevada (cerca del 15%) a otra sección de menos profundidad y más abierta que ha obligado a la toma de secciones transversales de gran longitud.

Para afinar el modelo, se han interpolado secciones transversales a partir de las obtenidas en cartografía cada 10 m, tal y como muestra la siguiente imagen.

Ilustración 3.- Modelo interpolado empleado en el cálculo. En verde claro se muestran las secciones interpoladas.



2.3.2. PENDIENTE LONGITUDINAL

Las pendientes longitudinales, obtenidas a partir de la topografía con que contamos, resultan ser las siguientes:

- Pendiente media del tramo 8,40 %
- Pendiente inicial 17,00 %
- Pendiente final 5,00%

Las pendientes de los tramos inicial y final serán las que se empleen como condiciones de contorno por ser las que mejor describen el comportamiento del río.

2.3.3. VEGETACIÓN

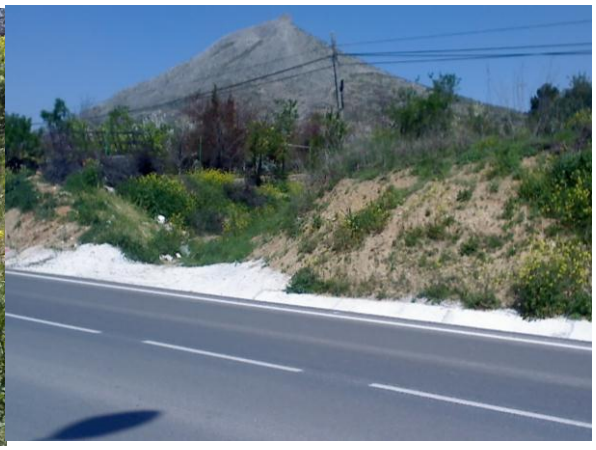
La vegetación, como puede comprobarse en las imágenes que siguen, no es excesiva en el cauce de aguas bajas. En cuanto a las márgenes son en su mayoría mosaicos de cultivos y olivares.

Se ha tenido en cuenta la presencia de estas masas arbustivas para la determinación del coeficiente de rugosidad, distinguiendo cauce principal y llanuras de inundación. Más adelante se detallarán los cálculos realizados.

A continuación se muestran varias imágenes que caracterizan la zona.

Ilustración 4. Aspecto del cauce del arroyo Larija

Ilustración 5. Desembocadura a la cuneta de la carretera JA-3305



3. METODOLOGÍA DE LA MODELIZACIÓN HIDRÁULICA

3.1. INTRODUCCIÓN

Se ha modelizado el régimen hidráulico del tramo de estudio del arroyo Larija a través del programa informático HEC-RAS 4.1.0. del U.S. Arms Corps Of Engineers.

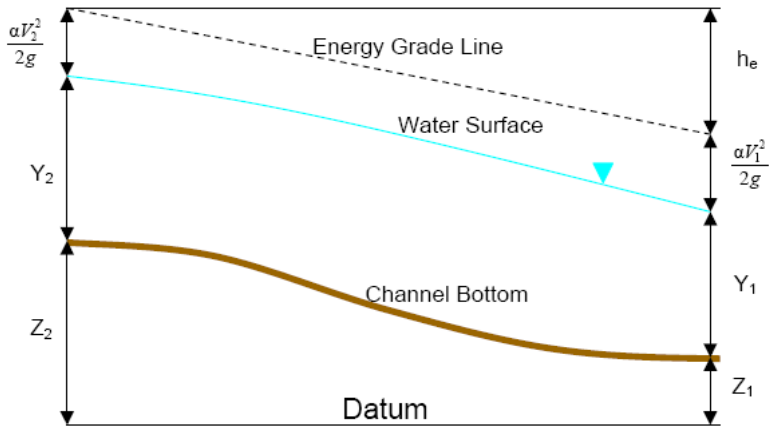
Los cálculos se realizan en régimen estacionario para las avenidas de 5 y 500 años. La primera simulación permitirá determinar el DPH, y la segunda, la llanura de inundación.

3.2. BASES DE CÁLCULO

El software utilizado realiza los cálculos para un nivel de agua unidimensional en cada sección transversal del cauce en régimen de flujo gradualmente variado. Las hipótesis básicas de partida son:

- Pérdidas de carga valoradas según Manning
- Flujo estacionario, el tiempo no interviene en los cálculos
- Flujo gradualmente variado
- Flujo unidimensional, la altura de la curva de energía es la misma en todos los puntos de la sección
- No se admite cambio de régimen en un mismo cálculo
- La pendiente de la línea de energía es constante entre dos secciones transversales

Ilustración 6. Modelo de Cálculo



Los niveles del agua en cada sección se calculan a partir de una sección transversal hacia la siguiente mediante la resolución de la ecuación de la Energía con un proceso iterativo llamado "Método de Grados Estándar". La ecuación de la energía se escribe como sigue:

Ecuación 1

$$WS_2 + \frac{\alpha_2 \cdot V_2^2}{2g} = WS_1 + \frac{\alpha_1 \cdot V_1^2}{2g} + h_e$$

donde:

WS_1, WS_2 elevaciones de superficie de agua en secciones transversales

V_1, V_2 velocidad media (descarga total/área total de caudal)

α_1, α_2 coeficientes de medida de velocidad

g aceleración gravitatoria

h_e pérdidas de energía en cabeza

Las pérdidas de energía principales entre dos secciones transversales se calculan como la suma de las pérdidas de fricción y las de contracción o expansión, y vienen dadas por la expresión:

Ecuación 2

$$h_e = LS_f + C\left|\frac{\alpha_2 \cdot V_2^2}{2g} - \frac{\alpha_1 \cdot V_1^2}{2g}\right|$$

donde

L longitud del tramo de desagüe

S_f pendiente de fricción representativa entre dos secciones

C coeficiente de pérdida por expansión o contracción (hace referencia al trazado en planta del tramo estudiado)

La determinación de la vehiculación total y el coeficiente de velocidad para una sección transversal requieren que el flujo sea subdividido en unidades para las que la velocidad esté uniformemente distribuida, unidades que vienen marcadas por los puntos de salto del valor n de Manning. La conducción se calcula dentro de cada subdivisión por la siguiente ecuación:

Ecuación 3

$$k = \frac{1.486}{n} \cdot AR^{2/3}$$

donde

K conducción por subdivisión

n coeficiente de rugosidad de Manning por subdivisión

A área de caudal por subdivisión

R radio hidráulico por subdivisión

El coeficiente de velocidad α se calcula basándose en la vehiculación en los tres elementos de caudal: margen izquierdo, margen derecho y canal. Se obtiene con la siguiente ecuación:

Ecuación 4

$$\alpha = \frac{(A_t)^2 \left[\frac{(K_{lob})^3 + (K_{ch})^3 + (K_{rob})^3}{(A_{lob})^2 \cdot (A_{ch})^2 \cdot (A_{rob})^2} \right]}{(K_t)^3}$$

donde

A_t área total de caudal de sección transversal

A_{lob}, A_{ch}, A_{rob}, áreas de caudal de margen izquierdo, canal principal y margen derecho, respectivamente

K_t conducción total de sección transversal

K_{lob}, K_{ch}, K_{rob}, conducción de margen izquierdo, canal principal y margen derecho, respectivamente

La pérdida de fricción se evalúa como el producto de S_f y L, donde S_f es la pendiente de fricción representativa para un tramo y se calcula como sigue:

Ecuación 5

$$S_f = \left(\frac{Q_1 + Q_2}{K_1 + K_2} \right)$$

La elevación de la superficie del agua desconocida en una sección se determina por una solución iterativa de las Ecuaciones 1 y 2. El procedimiento seguido es el siguiente:

1. Se supone una elevación de superficie de agua en la sección aguas arriba
2. Basándose en ese supuesto, se determina la conducción total correspondiente y el frente de velocidad
3. Con los valores del paso 2, se calcula S_f y se resuelve la ecuación 2 para h_e
4. Con los valores de 2 y 3 se resuelve la ecuación 1 para WS_2
5. Comparación del valor calculado de WS_2, con el valor supuesto en el paso 1, repitiendo los pasos hasta que los valores concuerden dentro de 0,003 m

El programa usado está restringido a un número máximo de iteraciones, 40 como máximo, para equilibrar la superficie del agua. Cuando se ha obtenido una cota elevación de superficie de agua 'equilibrada' para una sección transversal, se hacen las revisiones para asegurar que la elevación está en la zona correcta respecto de la profundidad crítica calculada.

En los apéndices que se incluyen al final del presente documento se adjuntan los listados y salidas del programa informático HEC-RAS. Estos constan de: descripción general de los datos de partida del modelo hidráulico, gráficas de las secciones de control introducidas, perfil hidráulico del tramo y perspectiva de la llanura de inundación.

3.3. COEFICIENTES DE ROZAMIENTO

El principal problema que se plantea al analizar un curso de agua natural, como ya hemos comentado, es la estimación del coeficiente de Manning, n, pues son muchos los factores que intervienen en su cálculo.

Al fijar un valor de n, lo que se está estimando es la resistencia al 'escurrimiento' del arroyo, algo realmente intangible.

Los factores que intervienen con mayor influencia son:

Rugosidad de la superficie: se refiere al tamaño y a la forma de los granos del material que forma el perímetro mojado. En corrientes aluviales en donde el material de los granos es fino, tal como la arena, arcilla, marga o cieno, el efecto retardante es mucho menor que donde el material es grueso, tal como cantos rodados o piedras. Cuando el material es fino, el valor de n es bajo y relativamente poco afectado por los cambios de flujo.

Vegetación: puede ser vista como una clase de rugosidad superficial, pues reduce en marcada forma la capacidad del canal y retarda el flujo. Este efecto depende principalmente de la altura, densidad, distribución y tipo de vegetación.

Irregularidad del cauce: comprende irregularidades en el perímetro mojado y variaciones en la sección transversal, tamaño y forma a lo largo de la longitud del cauce. En general, un cambio gradual y uniforme en la sección transversal, tamaño y forma no afectará apreciablemente al valor de n, pero cambios bruscos o alternación de secciones pequeñas y grandes justifican el uso de un valor superior de n.

Alineación del cauce: curvaturas suaves con radios grandes darán un valor relativamente bajo de n, mientras que curvaturas agudas con meandros severos lo aumentarán.

Depósitos y socavaciones: en términos generales, los depósitos pueden cambiar un cauce irregular en uno comparativamente suave y disminuir n, mientras que la erosión puede hacer al revés y aumentar n. Ahora bien, depósitos disparejos tales como barras y ondas de arena son irregularidades del cauce y aumentarán la rugosidad.

Obstrucción: la presencia de pilares de puentes tiende a aumentar n. Depende la naturaleza de la obstrucción, tamaño, forma, número y distribución.

Nivel y caudal: el valor de n en la mayoría de los cauces decrece con el aumento en el nivel y en el caudal.

En cada sección transversal del modelo se han fijado dos valores del rozamiento de Manning, siguiendo las recomendaciones del manual "Hidráulica de los Canales Abiertos" de Ven Te Chow.

$$n = (n_0 + n_1 + n_2 + n_3 + n_4) \cdot m_5$$

Son los que se describen a continuación:

ARROYO LARIJA

Tabla 2. Coeficientes de rozamiento para el canal central

MÁRGENES		
Variable	Tipo	Valor
Material	Tierra	$n_0 = 0.02$
Irregularidad	Moderada	$n_1 = 0.01$
Variaciones	Ocasionales	$n_2 = 0.005$
Obstrucciones	Menor	$n_3 = 0.01$
Vegetación	Media	$n_4 = 0.015$
Meandros	Menor	$m_5 = 1.00$
n = 0.06		

Tabla 3. Coeficientes de rozamiento para el canal central

CANAL CENTRAL		
Variable	Tipo	Valor
Material	Tierra	$n_0 = 0.02$
Irregularidad	Moderada	$n_1 = 0.01$
Variaciones	Ocasionales	$n_2 = 0.005$
Obstrucciones	Menor	$n_3 = 0.01$
Vegetación	Media	$n_4 = 0.01$
Meandros	Apreciable	$m_5 = 1.15$
n = 0.06		

3.4. CONDICIONES DE CONTORNO

Las condiciones de contorno se introducen tanto aguas arriba como aguas abajo del tramo modelizado. Son necesarias para el inicio del proceso iterativo de cálculo.

De las alternativas que contempla el programa se ha elegido la pendiente del eje del arroyo tanto para el inicio como para el final del tramo, descritas en el apartado 2 del presente Anejo.

4. ANÁLISIS DE LOS RESULTADOS OBTENIDOS

4.1. RESTRICCIONES DEL MODELO

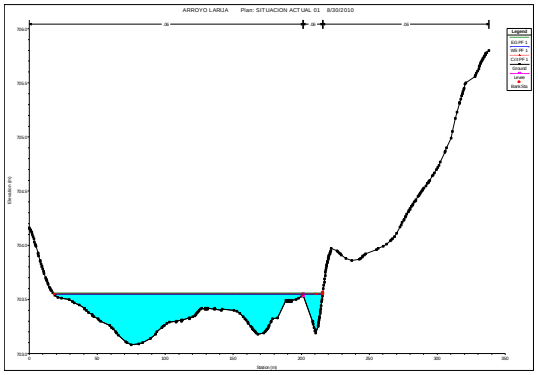
Antes de comentar los resultados obtenidos, es necesario aclarar que la precisión del modelo hidráulico no se corresponde con la precisión de la cartografía empleada, es decir, que como se ha partido de una cartografía a escala 1:2.000, con curvas de nivel equidistantes 1 metro, no podemos adoptar la escala milimétrica del modelo como valor absoluto.

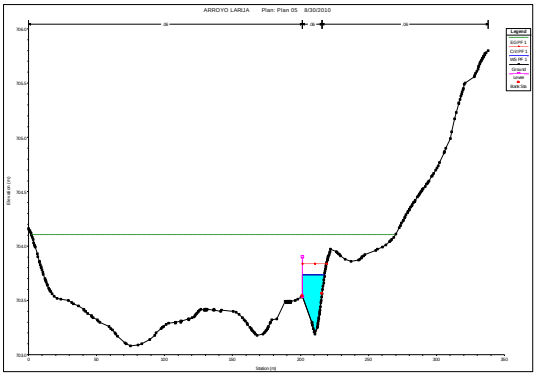
Ello nos ha llevado a adoptar motas en varias secciones para evitar que diferencias centimétricas entre el límite del cauce actual y la lámina de agua, extendiera la llanura de inundación varias decenas de metros. Estas motas se pueden consultar en el Apéndice 2, y en ningún caso superan los 25 cm, valor que entendemos razonable para el estudio de inundabilidad que nos ocupa, en el que se pretende delimitar la llanura de inundación de periodo de retorno 500 años.

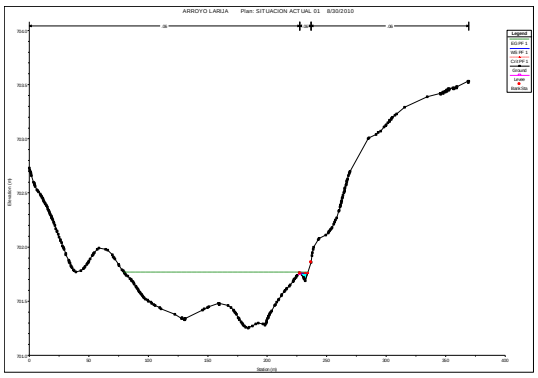
A modo de ejemplo, transcribimos las tres secciones más representativas de este fenómeno:

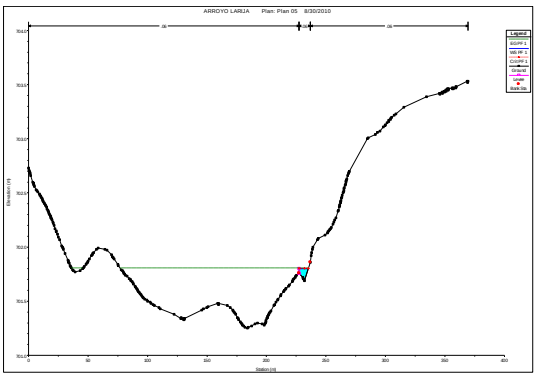
MODELO SIN MOTAS

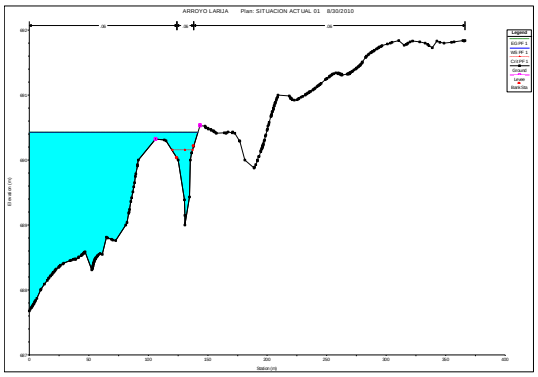
MODELO CON MOTAS ≤ 25cm

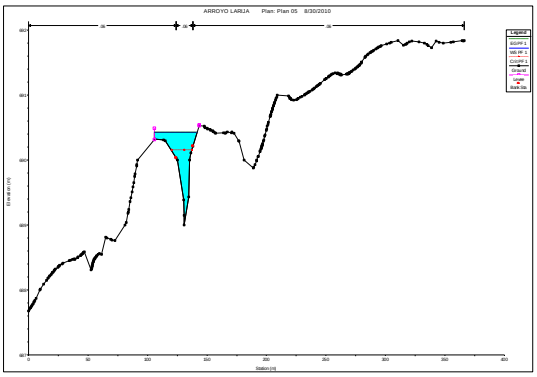












4.2. AVENIDA ORDINARIA DE PERIODO DE RETORNO 5 AÑOS

4.2.1. TABLA RESUMEN DE LOS RESULTADOS

Se adjunta la tabla resumen de los resultados obtenidos, así como las gráficas de velocidades y del nº de Froude.

Tabla 4.- Resumen del modelo para T=5años

Ilustración 7. Velocidades

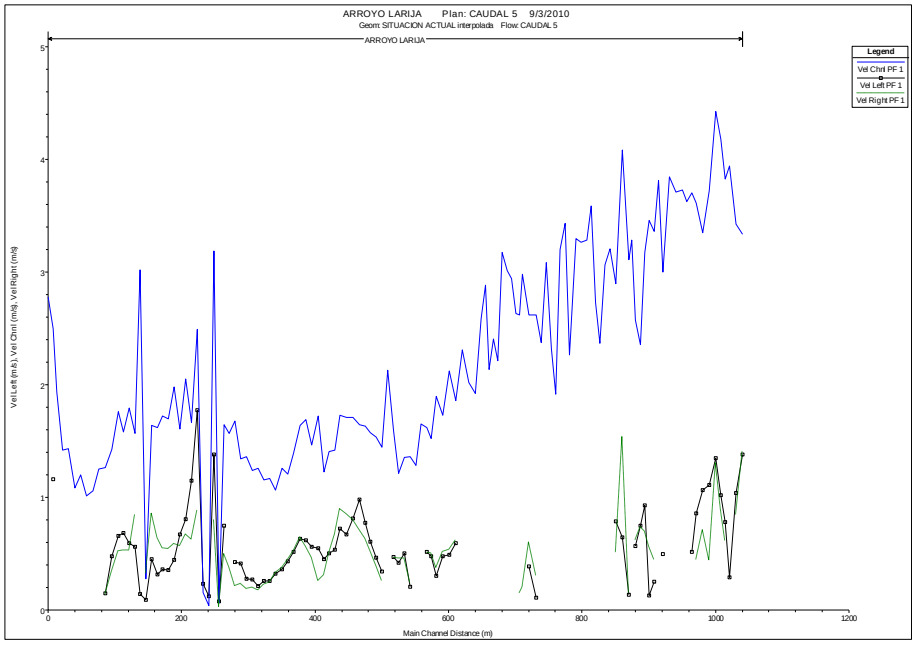

Ilustración 8. Froude

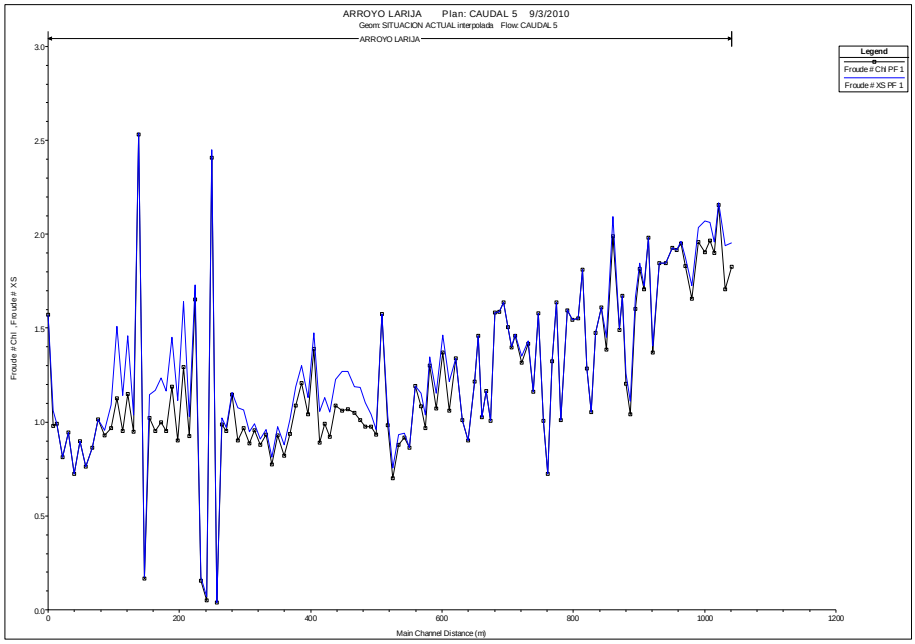


El régimen obtenido en el tramo de estudio del arroyo Larija es mayoritariamente supercrítico debido a las elevadas pendientes que presenta.

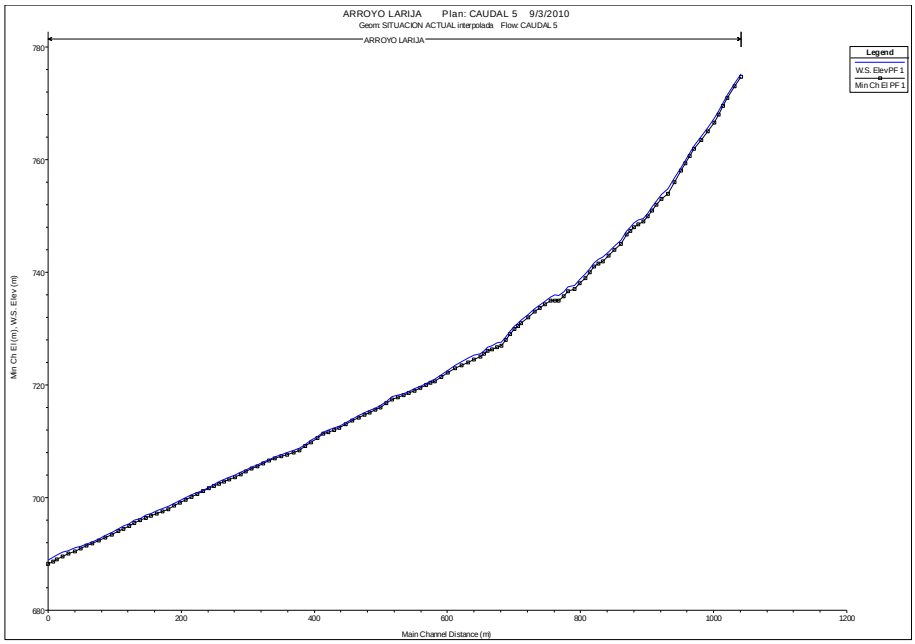
Las velocidades obtenidas en el canal principal son bastante elevadas aunque dispares (desde 2 a 6 m/s) y se observa claramente como el final del tramo el modelo presenta algunas irregularidades debido a la cartografía.

En los apéndices 2 a 4 del anejo se muestran el perfil hidráulico obtenido y las secciones hidráulicas resultantes, así como una descripción detallada tanto de los datos de partida como de los resultados obtenidos en la modelización.

4.2.2. ANÁLISIS DE COTAS DE INUNDACIÓN

A continuación se muestra el gráfico con las cotas de la llanura de inundación alcanzadas para la avenida ordinaria de 5 años de periodo de retorno:

Ilustración 9. Cotas de inundación del modelo



De este gráfico se extraen los valores de cota de lámina de agua en cada perfil para poder trasladarlos a planta y dibujar la llanura de inundación.

4.3. AVENIDA EXTRAORDINARIA DE PERIODO DE RETORNO 500 AÑOS

4.3.1. TABLA RESUMEN DE LOS RESULTADOS

Se adjunta la tabla resumen de los resultados obtenidos, así como las gráficas de velocidades y del nº de Froude.

El régimen obtenido en el tramo de estudio del arroyo Larija es mayoritariamente supercrítico debido a las elevadas pendientes que presenta.

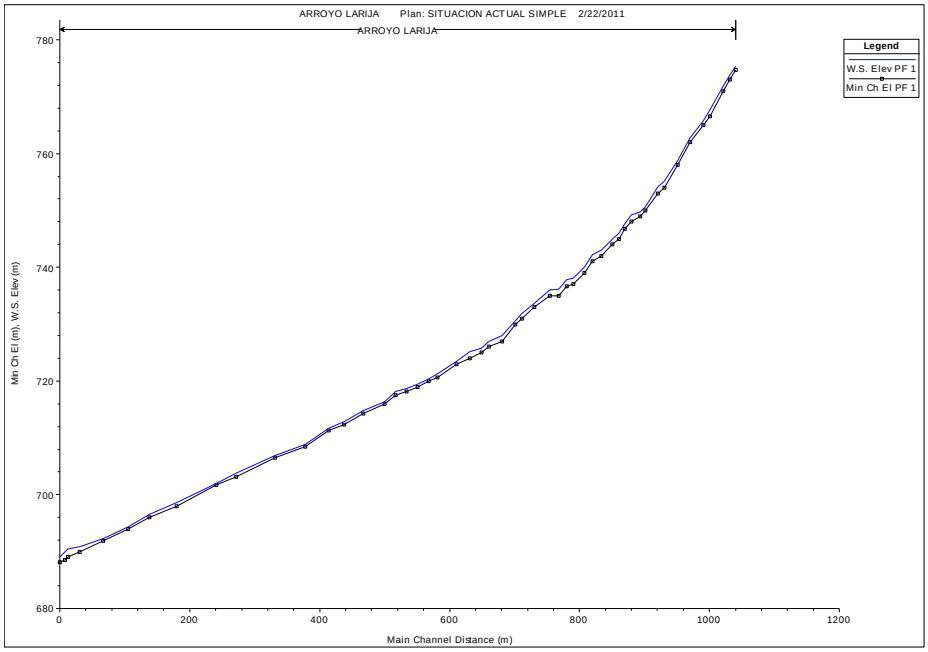
Las velocidades obtenidas en el canal principal son bastante elevadas aunque dispares (desde 2 a 6 m/s) y se observa claramente como el final del tramo el modelo presenta algunas irregularidades debido a la cartografía.

En los apéndices 2 a 4 del anejo se muestran el perfil hidráulico obtenido y las secciones hidráulicas resultantes, así como una descripción detallada tanto de los datos de partida como de los resultados obtenidos en la modelización.

4.3.2. ANÁLISIS DE COTAS DE INUNDACIÓN

A continuación se muestra el gráfico con las cotas de la llanura de inundación alcanzadas para la avenida extraordinaria de 500 años:

Ilustración 12. Cotas de inundación del modelo



De este gráfico se extraen los valores de cota de lámina de agua en cada perfil para poder trasladarlos a planta y dibujar la llanura de inundación.

4.3.3. INCIDENCIAS CON LA ORDENACIÓN EXISTENTE

Aunque este estudio complementa el documento del Plan General de Ordenación Urbanística en Martos y, por tanto, es en dicho documento donde se analizarán con detalle las posibles incidencias con la ordenación que se proponga, señalamos que, en el caso del Arroyo Larija, la llanura de inundación para la avenida extrarodinaria afecta a lo largo de sus últimos 100 metros aproximadamente, a algunas edificaciones aisladas existentes en la zona.

La ordenación urbanística de los sectores de suelo urbanizable limítrofes al arroyo y a los terrenos inundables determinados en este estudio, tendrá en cuenta la integración paisajística con este espacio natural.

El modelo estudiado finaliza en la calle Príncipe Felipe, punto en el que el arroyo Larija se incorpora a la cuneta existente en la margen izquierda de la vía.

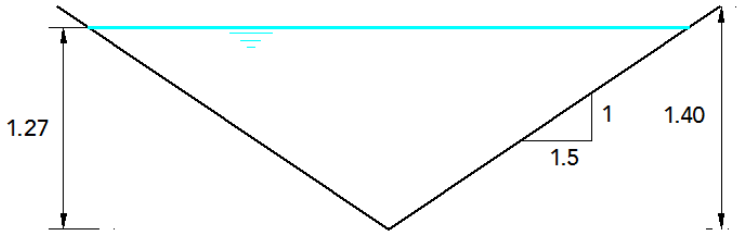
Ilustración 13. Desembocadura del Arroyo Larija a la cuneta de la JA-3305, denominada calle Príncipe Felipe

La capacidad actual de la cuneta no permite conducir la avenida extraordinaria de periodo de retorno 500 años del arroyo Larija.

Ilustración 14.- Aspecto actual de la cuneta. Se encuentra en buen estado y dispone de pendiente suficiente (2%)

Se hace necesaria, por tanto la ampliación de la cuneta. Se propone la siguiente sección tipo:

Ilustración 15. Propuesta acondicionamiento en tramo cuneta



Esta ampliación de la cuneta existente se integrará en el ámbito y en la ordenación de los sectores de suelo urbano no consolidado y urbanizable limítrofes.

Los justificación de la capacidad de la sección propuesta se adjunta a continuación.

Run Date and Time: 2/22/2011 7:03:14 PM

Project in SI units

PLAN DATA

Plan Title: SITUACION ACTUAL SIMPLE
Plan File : C:\RAS\LARIJA lourdes\Larija04.p02

           Geometry Title: SITUACION ACTUAL MOTAS 25 SIMPLE
           Geometry File : C:\RAS\LARIJA lourdes\Larija04.g03

           Flow Title    : CAUDAL 500
           Flow File     : C:\RAS\LARIJA lourdes\Larija04.f01

Plan Summary Information:
Number of:  Cross Sections =   51    Multiple Openings  =    0
            Culverts       =    0    Inline Structures  =    0
            Bridges        =    0    Lateral Structures =    0

Computational Information
    Water surface calculation tolerance  =  0.005
    Critical depth calculation tolerance =  0.003
    Maximum number of iterations         =  40
    Maximum difference tolerance         =  0.1
    Flow tolerance factor                =  0.001

Computation Options
    Critical depth computed at all cross sections
    Conveyance Calculation Method: At breaks in n values only
    Friction Slope Method:         Average Conveyance
    Computational Flow Regime:     Mixed Flow
